

DSE2023 - Deep Learning for Solving and Estimating Dynamic Models August 21th – 26<sup>th</sup>, 2023, HEC Lausanne

#### Simon Scheidegger (UNIL)

Marlon Azinović (UPenn)

Luca Gaegauf (UZH)

# DSE 2023 – Day 2 (August 22<sup>nd</sup>)

			Tuesday, 22 August	
9:00	10:20	Lecture 6	Deep Equilibrium Nets	Simon Scheidegger
10:30	11:50	Lecture 7	DeepHAM: A global solution method for heterogeneous agent models with aggregate shocks	Yucheng Yang
11:50	13:00	Lunch		
13:00	14:20	Lecture 8	Deep Uncertainty Quantification: With an Application to Integrated Assessment Models	Felix Kubler
14:30	15:50	Lecture 9	Exploiting symmetry in high-dimensional DP models	Jesus Fernandez-Villaverde
16:00	17:20	Lecture 10	Using deep learning to solve heterogeneous agents dynamic equilibrium problems.	Jesus Fernandez-Villaverde
18:00		Social Event	Informal hang-out for students (location organized by local Ph.D. students)	

#### **Outline**

- 1. Motivation why are we doing what we are doing
- 2. Technical background of "Deep Equilibrium Nets"
  - 2. I. From artificial neural networks to "Deep Equilibrium Nets".
  - 2. II. A simple benchmark model (Brock & Mirman (1972)) Notebook: code/01\_Brook\_Mirman\_1972\_DEQN.ipynb
  - 2. III. A stochastic benchmark model (based on Brock & Mirman (1972)) Notebook: code/02\_Brock\_Mirman\_Uncertainty\_DEQN.ipynb
  - 2. IV. A simple benchmark OLG model (take-home slides due to limited time).

#### <u>Humans are all different – heterogeneous</u>

- **Heterogeneity** a crucial ingredient in contemporary models:
  - to study e.g. cross-sectional consumption response to aggregate shocks.
  - to model, e.g., social security.
- Example OLG models:
  - → How many age groups?
  - → borrowing constraints?
  - → aggregate shocks?
  - → idiosyncratic shocks?
  - → liquid / illiquid assets\*\*?
  - → Models: heterogeneous & high-dimensional

#### U.S. Total Money Income Distribution by Age, 2012 \$120,000 \$110,000 \$100,000 \$90,000 Percentile \$80,000 —10th fotal Money Income -20th \$70,000 -30th \$60,000 -40th \$50,000 —50th ---60th \$40,000 —70th \$30,000 ---80th -90th \$20,000 \$10,000 \$0 70-74

### **Dynamic Stochastic Models**

e.g. Judd (1998), Ljungquist & Sargent (2004),...

$$\mathbb{E}\left[E\left(\mathbf{x}_{t}, \mathbf{x}_{t+1}, p\left(\mathbf{x}_{t}\right), p\left(\mathbf{x}_{t+1}\right)\right) | \mathbf{x}_{t}, p\left(\mathbf{x}_{t}\right)\right] = 0$$

$$\mathbf{x}_{t+1} \sim \mathcal{P}\left(\cdot | \mathbf{x}_t, p\left(\mathbf{x}_t\right)\right)$$

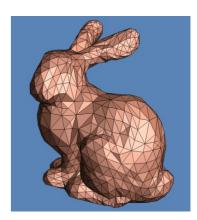

State-space potentially irregularly-shaped and high-dimensional.

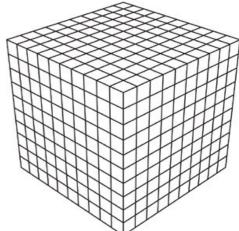

high-dimensional functions on which we interpolate.

- $\rightarrow$  N<sup>d</sup> points in ordinary discretization schemes.
- → "Curse of dimensionality".
- → Usually: solve many non-linear systems of equations by invoking a solver.

# What is high-dimensional?

<b>#State Variables (Dimensions)</b>	<u>#Points</u>	Time-to-solution
1	10	10 sec
2	100	~ 1.6 min
3	1,000	~ 16 min
4	10,000	~ 2.7 hours
5	100,000	~ 1.1 days
6	1,000,000	~ 1.6 weeks
20	1e20	3 trillion years (240x age of the universe)

#### **Dimension reduction**

Exploit symmetries, e.g., via the active subspace method

#### **Deal with #Points**

e.g., via (Smolyak/adpative) sparse grids

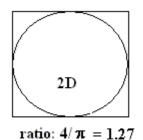

#### **High-performance computing**

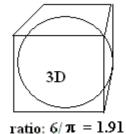

Reduces time to solution, but not the problem size

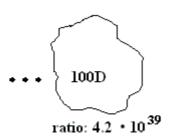

### Volumes in high dimensions

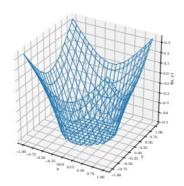

- Consider a cube of unit lengths containing a sphere of unit radius in higher dimensions.
- For large dimensions: ratio

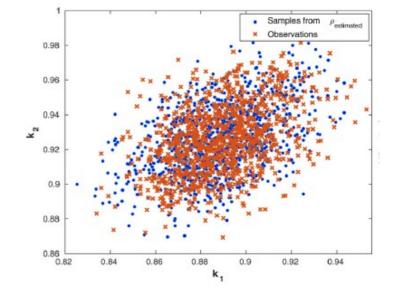

#### Volume(Sphere)/Volume(Cube) → 0

Scheidegger & Bilionis (2019)

#### **Abstract Problem Formulation**

- i) Contemporary dynamic models: heterogeneous & high-dimensional
- ii) Want to compute global solutions to dynamic stochastic models with high-dimensional state spaces
- → Have to approximate and interpolate high-dimensional functions on irregular-shaped geometries
- → Problem: curse of dimensionality
- iii) Want to alleviate the curse of dimensionality
- iv) Want locality of approximation scheme
- v) Speed-up → potentially access contemporary HPC systems

# Our solution: Deep Equilibrium Nets

- → Solving, e.g., rich OLG models numerically is a **formidable task**.
- → Models are often formulated in a **stylized** fashion to remain computationally **tractable**.
- → We develop a generic solution framework based on neural networks to solve highly-complex dynamic stochastic models.

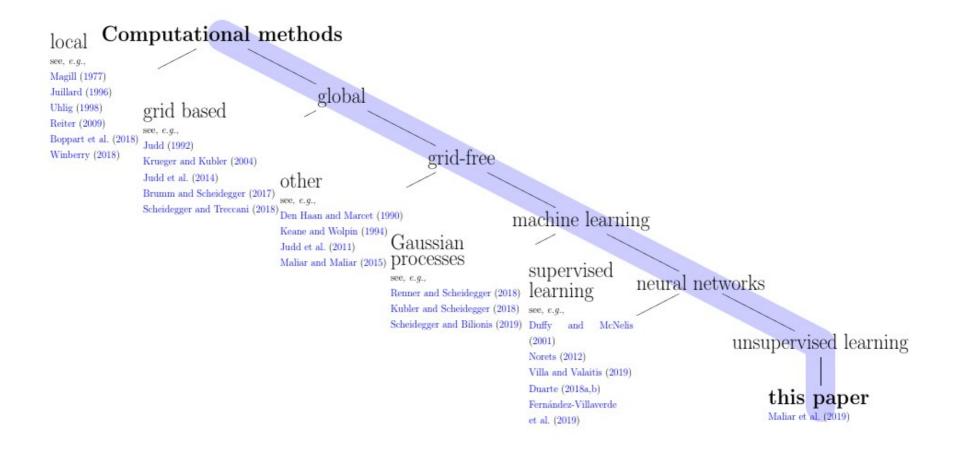

#### **Key ideas:**

- 1. Use the the implied error in the optimality conditions, as loss function.
- 2. Learn the equilibrium functions with stochastic gradient descent.
- 3. Take the (training) data points from a simulated path
  - → can be generated at virtual zero cost.

# 2. Technical Background

### An incomplete list of related literature

# Recall: what is a deep neural network

see, e.g., Cybenko (1989), Hornik (1991)

- Neural networks are flexible function approximators.
- A neural net is characterized by its parameters p.
- Given a parameter vector  $\mathbf{p}$  and input vector  $\mathbf{x}$ , denote the neural net as  $\mathcal{N}_{\mathbf{p}}$ , and some desired function with  $\mathbf{f}$ .

$$egin{aligned} \mathcal{N}_{
ho}: \mathbb{R}^{N_{ ext{in}}} &
ightarrow \mathbb{R}^{N_{ ext{out}}}: \mathbf{x} 
ightarrow \mathcal{N}_{
ho}(\mathbf{x}) \ \mathbf{f}(\mathbf{x}): \mathbb{R}^{N_{ ext{in}}} &
ightarrow \mathbb{R}^{N_{ ext{out}}}: \mathbf{x} 
ightarrow \mathbf{f}(\mathbf{x}) \end{aligned}$$

• We desire parameters  $\rho$ , such that

$$\|\mathcal{N}_{\rho} - \mathbf{f}\|_{\text{some norm}} = 0$$

# What is a deep neural network?

#### Consider:

input := 
$$\mathbf{x} \to W_{\rho}^{1}\mathbf{x} + \mathbf{b}_{\rho}^{1}$$
 =: hidden 1  
 $\to$  hidden 1  $\to W_{\rho}^{2}$ (hidden 1)  $+ \mathbf{b}_{\rho}^{2}$  =: hidden 2  
 $\to$  hidden 2  $\to W_{\rho}^{3}$ (hidden 2)  $+ \mathbf{b}_{\rho}^{3}$  =: output

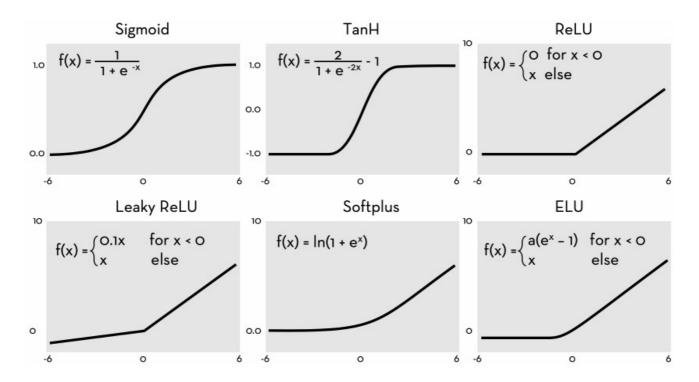

The parameters  $\rho$  are the entries of the matrices  $\left(W_{\rho}^{1},W_{\rho}^{2},W_{\rho}^{3}\right)$  and vectors  $\left(\mathbf{b}_{\rho}^{1},\mathbf{b}_{\rho}^{2},\mathbf{b}_{\rho}^{3}\right)$ 

### What is a deep neural network?

So far we have a concatenation of affine maps and therefore an affine map.

Next ingredient: **activation functions**  $\phi^1, \phi^2, \phi^3$ 

Popular activation functions are:

### What is a deep neural network?

Now we obtain:

input := 
$$\mathbf{x} \to \phi^1(W_\rho^1\mathbf{x} + \mathbf{b}_\rho^1)$$
 =: hidden 1  
 $\to$  hidden  $\mathbf{1} \to \phi^2(W_\rho^2(\text{hidden 1}) + \mathbf{b}_\rho^2)$  =: hidden 2  
 $\to$  hidden  $\mathbf{2} \to \phi^3(W_\rho^3(\text{hidden 2}) + \mathbf{b}_\rho^3)$  =: output

The **neural net** is then given by the choice of **activation functions** and the **parameters**  $\rho$ .

# How to find good parameters ρ?

#### **The standard way:**

Step 1: get "labelled data"  $\mathcal{D} := \{(\mathbf{x}_1, \mathbf{y}_1), \dots, (\mathbf{x}_{|\mathcal{D}|}, \mathbf{y}_{|\mathcal{D}|})\}$  where  $\mathbf{y}_i = \mathbf{f}(\mathbf{x}_i)$  is the correct output  $\rightarrow$  Supervised learning

Step 2: Define a loss function, for example:

$$l_{\rho} := \frac{1}{|\mathcal{D}|} \sum_{(\mathbf{x}_{i}, \mathbf{y}_{i}) \in \mathcal{D}} (\mathbf{y}_{i} - \mathcal{N}_{\rho}(\mathbf{x}_{i}))^{2}$$

Step 3: Adjust the parameters to minimize the loss via (stochastic) gradient descent:

$$\rho_i^{\text{new}} = \rho_i^{\text{old}} - \alpha^{\text{step}} \frac{\partial l_{\rho}^{\text{old}}}{\partial \rho_i^{\text{old}}}$$

the step-width  $\alpha^{\text{step}}$  is called the "learning rate" and the process of adjusting the parameters is called "learning".

# How to find good parameters ρ?

 The deeper and larger the neural net becomes, the more flexible it is as a function approximator, ...

... but the more data it will need

- → rule of thumb: #observations/parameters ~ 10x (Marsland (2014).
- In economic applications, the standard way of solving for equilibria is to use time iteration → "small" data.

(e.g., Sparse Grids (Brumm & Scheidegger (2017), Krüger & Kübler (2004), Judd et al. (2014))

#### The issue with time iteration

• Time Iteration – collocation (see, e.g., Judd (1998), and references therein)

- 1. Select a grid G, and a policy function  $f^{\text{start}}$ . Set  $f^{\text{next}} \equiv f^{\text{start}}$
- 2. Make one time iteration step:
  - 1. For all  $g \in G$ , find f(g) that solves the Period-to-Period Equilibrium Problem given  $f^{\text{next}}$  .
  - 2. Use solutions at all grid points G to interpolate f(how?).
- 3. Check error criterion: If  $||f f|^{\text{next}}||_{\infty} < \epsilon$ , report solution:  $\tilde{f} = f$  Else set  $f^{\text{next}} \equiv f$  and go to step 2.
- → Solving non-linear sets of equations in every iteration can be a daunting task.
- → What if non-linear solver does not converge? Construction of approximator may crash.
- → Can the dynamic economic problem at hand be mapped onto a grid?

#### An "economic" loss function

Novelty: we propose an "economic" loss function:

$$l_{\rho} := \frac{1}{N_{\text{ path length}}} \sum_{\mathbf{x_i \text{ on sim. path}}} (\mathbf{G}(\mathbf{x}_i, \mathcal{N}_{\rho}(\mathbf{x}_i)))^2$$

where we use  $\mathcal{N}_{\rho}$  to simulate a path.

• **G** is chosen such that the **true equilibrium policy f(x)** is defined by

$$G(x, f(x)) = 0 \ \forall x.$$

- G(.,.): implied error in the optimality conditions (unit-free Euler errors)
- Therefore, there is **no need for labels** to evaluate our loss function.
  - → Unsupervised Machine Learning.

### Training Deep Equilibrium Nets

```
Algorithm 1: Algorithm for training deep equilibrium nets.
  Data:
  T (length of an episode),
  N^{\text{epochs}} (number of epochs on each episode),
  \tau^{\text{max}} (desired threshold for max error),
  \tau^{\text{mean}} (desired threshold for mean error),
  \epsilon^{\text{mean}} = \infty (starting value for current mean error),
  \epsilon^{\max} = \infty (starting value for current max error),
  N^{\text{iter}} (maximum number of iterations),
  \rho^0 (initial parameters of the neural network),
  \mathbf{x}_{1}^{0} (initial state to start simulations from),
  i = 0 (set iteration counter),
  \alpha^{\text{learn}} (learning rate)
  Result:
  success (boolean if thresholds were reached)
  \rho^{\text{final}} (final neural network parameters)
  while ((i < N^{iter}) \land ((\epsilon^{mean} \ge \tau^{mean}) \lor (\epsilon^{max} \ge \tau^{max}))) do
        \mathcal{D}_{\text{train}}^i \leftarrow \{\mathbf{x}_1^i, \mathbf{x}_2^i, \dots, \mathbf{x}_T^i\} (generate new training data by simulating an episode of T periods as
          implied by the parameters \rho^i)
        \mathbf{x}_0^{i+1} \leftarrow \mathbf{x}_T^i (set new starting point)
        \epsilon_{\max} \leftarrow \max \left\{ \max_{\mathbf{x} \in \mathcal{D}_{\text{train}}^i} |e_{\mathbf{x}}^{\cdots}(\boldsymbol{\rho})| \right\} \text{ (calculate max error on new data)}
        \epsilon_{\text{mean}} \leftarrow \max \left\{ \frac{1}{T} \sum_{\mathbf{x} \in \mathcal{D}_{\text{train}}^i} | e_{\mathbf{x}}^{\cdots}(\boldsymbol{\rho}) | \right\}  (calculate mean error on new data)
        for j \in [1, ..., N^{epochs}] do
              (learn N^{\text{epochs}} on data)
              for k \in [1, ..., length(\boldsymbol{\rho})] do
                                                                    \rho_k^{i+1} = \rho_k^i - \alpha^{\text{learn}} \frac{\partial \ell_{\mathcal{D}_{\text{train}}^i}(\boldsymbol{\rho}^i)}{\partial \rho_i^i}
                    (do a gradient descent step to update the network parameters)
              end
        i \leftarrow i + 1 (update episode counter)
  if i = N^{iter} then return (success \leftarrow False, \rho^{final} \leftarrow \rho^{i});
  else return (success \leftarrow True, \rho^{\text{final}} \leftarrow \rho^{i});
```

### 2. II. A simple benchmark model

Lets check-out the notebook: code/01\_Brook\_Mirman\_1972\_DEQN.ipynb

#### Simple Introduction to Deep Equilibrium Nets

#### Notebook 1: no uncertainty and exogenous sampling of states

Notebook by Marlon Azinovic, Luca Gaegauf, and Simon Scheidegger, August 2023.

#### Purpose of the notebook and economic model

The notebook should serve as a simple introduction to <u>Deep Equilibirium Nets</u>, a deep learning based method introduced in <u>Azinovic et al. (2022)</u>. To focus on the method, we are going to solve a simple optimal growth model with one representative agent, a simplified version of <u>Brock and Mirman (1972)</u>.

The planner aims to maximize her time-separable life time utility subject to her budget constraint:

$$\max_{\{c_t\}_{t=0}^{\infty}} \sum_{t=0}^{\infty} \beta^t \ln(C_t)$$
s.t.  $K_{t+1} + C_t = Y_t + (1 - \delta)K_t$ 

where  $Y_t = K_t^{\alpha}$ .

When we assume full depreciation, i.e.  $\delta = 1$ , this particular problem has an analytical solution:

$$K_{t+1} = \beta \alpha K_t^{\alpha}$$

We can numerically solve the above planner's problem by using any global solution algorithm such as the value function iteration or the time iteration collocation.

However in this notebook, we demonstrate how the recursive equilibrium can be directly approximated by the deep neural net following <u>Azinovic et al.</u> (2022).

### 2. III. A simple stochastic model

#### Lets check-out the notebook: code/02\_Brock\_Mirman\_Uncertainty\_DEQN.ipynb

#### Simple Introduction to Deep Equilibrium Nets

#### Notebook 2: uncertainty and sampling states from the simulated path of the economy

Notebook by Marlon Azinovic, Luca Gaegauf, and Simon Scheidegger, August 2023.

#### Purpose of the notebook and economic model

where now

The notebook is the second of three notebooks that should serve as a simple introduction to <u>Deep Equilibirium Nets</u>, a deep learning based method introduced in Azinovic et.al (2022).

To focus on the method, we are going to solve a simple optimal growth model with one representative agent, a simplified version of <u>Brock and Mirman</u> (1972).

The previous notebook introduced the method in a setting with a single state variable ( $\mathbf{X}_t = K_t$ ), without any uncertainty, and with sampling the states of the economy from an exogenously given interval  $\mathcal{K} = [K, \overline{K}]$ .

In this notebook we take the model a step further by introducing two new aspects.

- 1. We introduce **aggregate uncertainty** in form of an AR(1) process for the log of total factor productivity ( $\log(z_t)$ ). The evaluation of the equilibrium hence involves the evaluation of an expectation operator requiring **numerical integration**. Furthermore, the state space will become two dimensional ( $\mathbf{X}_t = [z_t, K_t]$ ).
- 2. The second new aspect we introduce is to sample the states, which we train the neural network on, from **simulated paths** of the economy. This is especially usefull when the state-space becomes high-dimensional. Since the state variables of economic models are often heavily correlated, training the neural network on a hyper-cubic domain is often exponentially wasteful (see <u>Maliar et al (2011)</u> for more information on this topic).

Similarly to the previous notebook the planner aims to maximize his time-separable life time utility subject to her budget constraint:

$$\max_{\{c_t\}_{t=0}^{\infty}} \sum_{t=0}^{\infty} \beta^t E\left[\ln(C_t)\right]$$
s.t. 
$$K_{t+1} + C_t = Y_t + (1 - \delta)K_t$$

$$Y_t = z_t K_t^{\alpha}$$

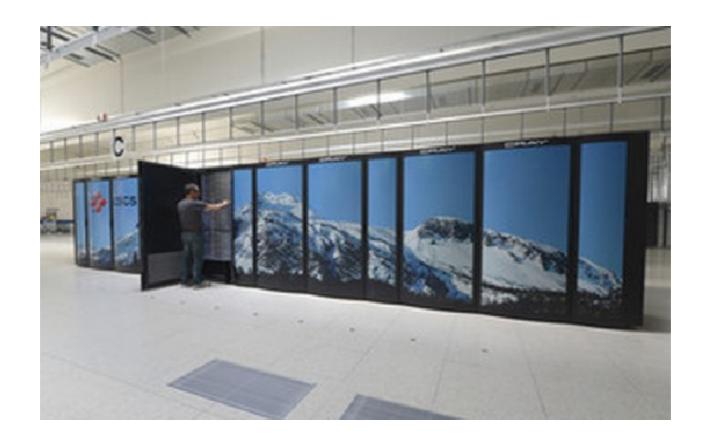

$$\log(z_t) = \rho \log(z_{t-1}) + \sigma \epsilon_t$$

$$\epsilon_t \sim N(0, 1).$$

The difference to the previous notebook is that production now depends on a random variable,  $z_t$ , which (in logs) follows an AR(1) process with persistence  $\rho$  and with a standard deviation of innovations given by  $\sigma$ . The case, where  $\rho = 1$  and  $\sigma = 0$ , corresponds to the certainty case solved in the previous notebook.

# "To pull a bigger wagon, it is easier to add more oxen than to grow a gigantic ox"

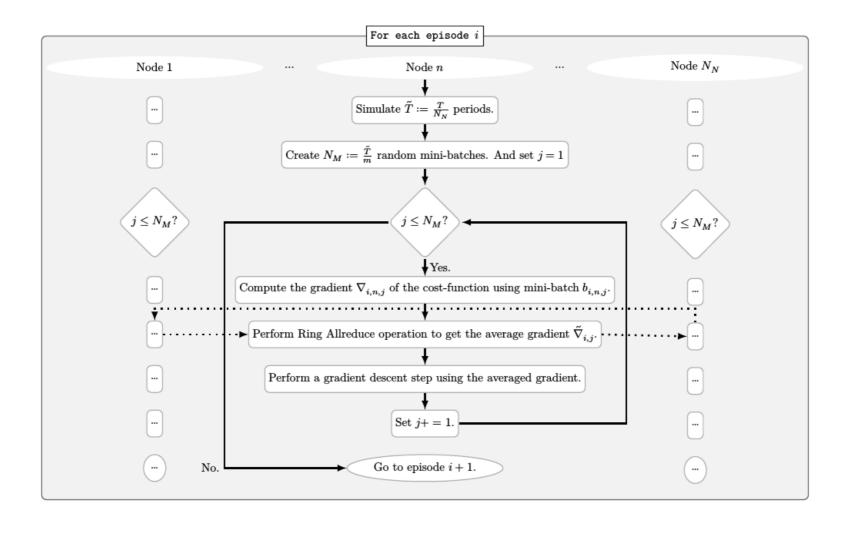

(Skjellum et al. 1999)

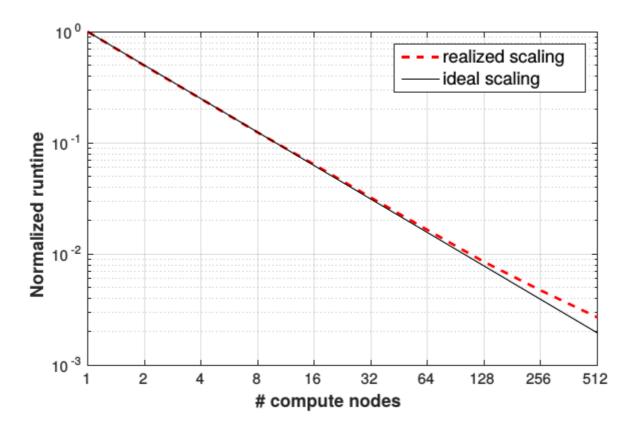

- We use Horovod to parallelize DEQ.
- Based on MPI.
- Idea: use data-parallelism.
- → The generation of training data is divided across compute nodes.
- → Each node computes the gradient of the cost-function concerning the parameters of the neural network on it's given batch of data.
- → Then, all nodes are synchronized and the gradient descent step is taken using the average gradient.

#### Parallelization Scheme

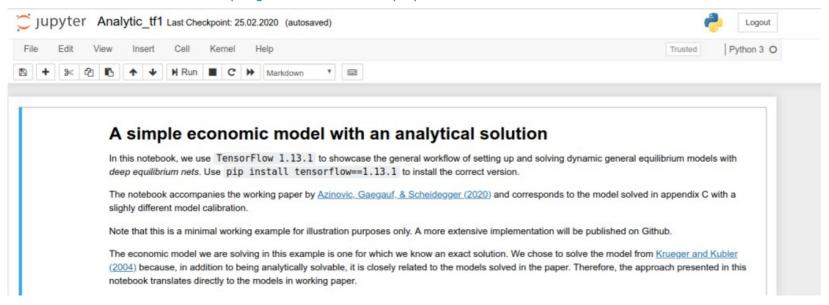

# Scalability on "Piz Daint" (CSCS)

- Excellent strong scaling efficiency (over 70% at 512 nodes).

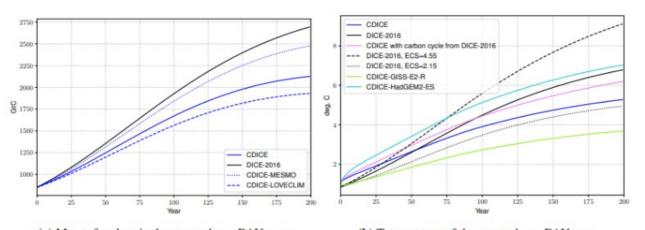

#### More DEQN codes available

Download it here: https://github.com/sischei/DeepEquilibriumNets

#### The Climate in Climate Economics

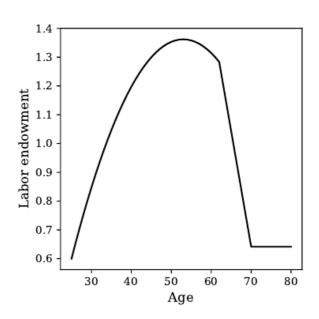

(a) Mass of carbon in the atmosphere, BAU case

(b) Temperature of the atmosphere, BAU case

# 2.IV. A benchmark OLG model (take-home material)

- Time is discrete:  $t = 0, \dots, \infty$
- Agents live for **N** periods (N=60 years).
- One representative household per cohort.
- Every *t*, a representative household in born.
- No uncertainty about lifetime.
- There are exogenous aggregate shocks **z** that follow a Markov chain.
- Each period, the agents alive receive a strictly positive labour endowment which depends on the age of the agent alone.

#### <u>Households</u>

- Household supplies its labour endowment inelastically for a market wage  $\mathbf{w}_t$ .
- Agents (with current age s) alive maximize their remaining time-separable discounted expected lifetime utility ( $\beta$  < 1):

$$\sum_{i=0}^{N-s} \mathcal{E}_t \left[ \beta^i u \left( c_{t+i}^{s+i} \right) \right] \tag{1}$$

- Households can save a unit of consumption good to obtain a unit of capital good next period (denoted as  $a_t^s$ ).
- The savings will become capital in the next period:

$$a_t^s = k_{t+1}^{s+1}, \forall t, \forall s \in \{1, \dots, N-1\}$$
 (2)

# Households (II)

- Households cannot die with debt.
- Borrowing is allowed up to an exogenously given level:  $a_t^s \ge \underline{a}$ . (3)
- At time t, the households sell their capital to the firm at market price  $\mathbf{r}_t > 0$ .
- The budget constraint of the household **s** in period *t* is

$$c_t^s + a_t^s = r_t k_t^s + l_t^s w_t (4)$$

- The agents are born, and die without any assets  $k_t^1 = 0$  and  $a_t^N = 0$ 

#### Firms & Markets

- There is a single representative firm with Cobb-Douglas production.
- The total factor productivity  $\eta$  (TFP) and the depreciation  $\delta$  depend on the exogenous shock z alone ( $\eta(z) \in \{0.85, 1.15\}, \delta(z) \in \{0.5, 0.9\}$ )

$$\pi^{\delta} = \begin{bmatrix} 0.98 & 0.02 \\ 0.25 & 0.75 \end{bmatrix}, \qquad \pi^{\eta} = \begin{bmatrix} 0.5 & 0.5 \\ 0.5 & 0.5 \end{bmatrix} \qquad z^{\delta} \otimes z^{\eta} = z \in \{0, 1, 2, 3\}$$

- Each period, after the shock has realized, the firm buys capital and hires labour to maximize its profits, taking prices as given.
- The stochastic production function is given by

$$f(K, L, z) = \eta(z)K^{\alpha}L^{1-\alpha} + K(1 - \delta(z))$$

- There are competitive spot markets for consumption, capital, labor.

# Equilibrium

**Definition 1 (competitive equilibrium)** A competitive equilibrium, given initial conditions  $z_0, \{k_0^s\}_{s=1}^{N-1}$ , is a collection of choices for households  $\{(c_t^s, a_t^s)_{s=1}^N\}_{t=0}^{\infty}$  and for the representative firm  $(K_t, L_t)_{t=0}^{\infty}$  as well as prices  $(r_t, w_t)_{t=0}^{\infty}$ , such that

- 1. Given  $(r_t, w_t)_{t=0}^{\infty}$ , the choices  $\{(c_t^s, a_t^s)_{s=1}^N\}_{t=0}^{\infty}$  maximize (1), subject to (2), (3), and (4).
- 2. Given  $r_t$ ,  $w_t$ , the firm maximizes profits, i.e.,

$$(K_t, L_t) \in \operatorname*{arg\,max}_{K_t, L_t \ge 0} f(K_t, L_t, z_t) - r_t K_t - w_t L_t.$$

3. All markets clear: For all t

$$L_t = \sum_{s=1}^{N} l_t^s,$$
$$K_t = \sum_{s=1}^{N} k_t^s,$$

$$K_t = \sum_{s=1}^{N} k_t^s$$

- (1): max. remaining lifetime utility
- (2): savings → capital in next period
- (3): borrowing constraint.
- (4): budget constraint.

### **Equilibrium Conditions**

- The first order conditions of the firms maximization problem imply

$$w(z^{t}) = (1 - \alpha)\eta(z_{t})K(z^{t})^{\alpha}L(z^{t})^{-\alpha}$$
$$r(z^{t}) = \alpha\eta(z_{t})K(z^{t})^{\alpha-1}L(z^{t})^{1-\alpha} + (1 - \delta(z_{t}))$$

- Optimality conditions for any given generation of age  $s \in 1, ..., N-1$ :

$$u'\left(c^{s}\left(z^{t}\right)\right) = \beta E_{z_{t}}\left[u'\left(c^{s+1}\left(z^{t}, z_{t+1}\right)\right) r\left(z^{t}, z_{t+1}\right)\right] + \lambda^{s}\left(z^{t}\right)$$

$$\lambda^{s}\left(z^{t}\right) \cdot \left(a^{s}\left(z^{t}\right) - \underline{a}\right) = 0$$

$$a^{s}\left(z^{t}\right) - \underline{a} \geq 0$$

$$\lambda^{s}\left(z^{t}\right) \geq 0$$

- The generation of terminal age N simply consumes everything it has.

#### Recall OLG: an explicit cost function

$$\ell_{\mathcal{D}_{\text{train}}}\left(\rho\right) := \frac{1}{|\mathcal{D}_{\text{train}}|} \frac{1}{N-1} \sum_{\mathbf{x}_{j} \in \mathcal{D}_{\text{train}}} \sum_{i=1}^{N-1} \left( \left(e_{\text{REE}}^{i} \left(\mathbf{x}_{j}\right)\right)^{2} + \left(e_{\mathbf{KKT}}^{i} \left(\mathbf{x}_{j}\right)\right)^{2} \right)$$

$$e_{\text{REE}}^{i}\left(\mathbf{x}_{j}\right) := \frac{u'^{-1}\left(\beta \mathbf{E}_{z_{j}}\left[r\left(\hat{\mathbf{x}}_{j,+}\right)u'\left(\hat{c}^{i+1}\left(\hat{\mathbf{x}}_{j,+}\right)\right)\right] + \hat{\lambda}^{i}\left(\mathbf{x}_{j}\right)\right)}{\hat{c}^{i}\left(\mathbf{x}_{j}\right)} - 1$$

$$e_{\mathbf{KKT}}^{i}(\mathbf{x}_{j}) := \hat{\lambda}^{i}(\mathbf{x}_{j}) \left(\hat{a}^{i}(\mathbf{x}_{j}) - \underline{a}\right)$$

$$\hat{\mathbf{x}}_{j,+} = \begin{bmatrix} z_+ \\ 0 \\ \hat{a}^{[1:N-1]}\left(\mathbf{x}_j\right) \end{bmatrix} \longrightarrow \text{Sampling from the relevant states}$$

#### Functional Rational Expectations Equilibrium

See, e.g., Spear (1988)

FREE: A function mapping states to policies that are consistent with the equilibrium conditions.

$$\mathbf{f}:\{0,1,2,3\}\times\mathbb{R}^{60}\to\mathbb{R}^{59\cdot 2}:\quad \mathbf{f}\left(\begin{bmatrix}z_t\\\mathbf{k}_t\end{bmatrix}\right)=\mathbf{f}\left(\begin{bmatrix}z_t\\k_t^2\\\ldots\\k_t^{59}\\k_t^{60}\end{bmatrix}\right)=\begin{bmatrix}a_t\\\ldots\\a_t^{59}\\\lambda_t^1\\\ldots\\\lambda_t^{59}\end{bmatrix} \text{ capital investment funct.}$$

such that:  $\forall h = 1, \ldots, 59$ :

$$0 = \beta \mathsf{E}_{t} \left[ \frac{R_{t+1}u'(c_{t+1}^{h+1}) + \lambda_{t}^{h}}{u'(c_{t}^{h})} \right] - 1$$

$$0 = \lambda_{t}^{h} a_{t}^{h}$$

$$0 \le \lambda_{t}^{h}$$

$$0 \le a_{t}^{h}$$

$$1 \le \mathsf{G} \left( \begin{bmatrix} z_{t} \\ \mathbf{k}_{t} \end{bmatrix}, \mathbf{f} \left( \begin{bmatrix} z_{t} \\ \mathbf{k}_{t} \end{bmatrix} \right) \right)_{h}$$

$$1 \le \mathsf{G} \left( \begin{bmatrix} z_{t} \\ \mathbf{k}_{t} \end{bmatrix}, \mathbf{f} \left( \begin{bmatrix} z_{t} \\ \mathbf{k}_{t} \end{bmatrix} \right) \right)_{h}$$

$$2 \le \mathsf{G} \left( \begin{bmatrix} z_{t} \\ \mathbf{k}_{t} \end{bmatrix}, \mathbf{f} \left( \begin{bmatrix} z_{t} \\ \mathbf{k}_{t} \end{bmatrix} \right) \right)_{h}$$

$$2 \le \mathsf{G} \left( \begin{bmatrix} z_{t} \\ \mathbf{k}_{t} \end{bmatrix}, \mathbf{f} \left( \begin{bmatrix} z_{t} \\ \mathbf{k}_{t} \end{bmatrix} \right) \right)_{h}$$

$$2 \le \mathsf{G} \left( \begin{bmatrix} z_{t} \\ \mathbf{k}_{t} \end{bmatrix}, \mathbf{f} \left( \begin{bmatrix} z_{t} \\ \mathbf{k}_{t} \end{bmatrix} \right) \right)_{h}$$

### <u>Deep Equilibrium Net – Architecture</u>

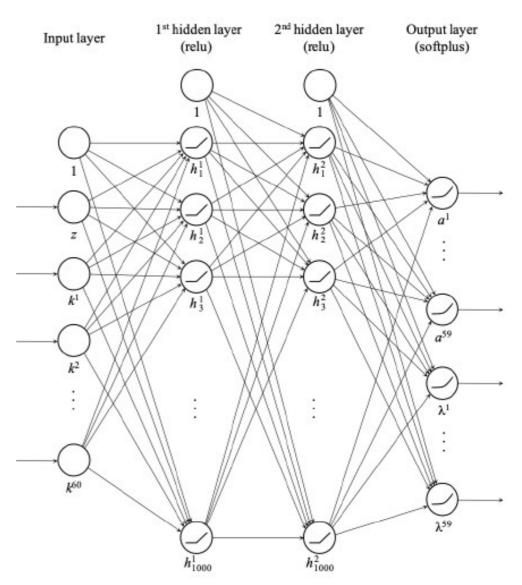

$$\mathcal{N}_{\boldsymbol{\rho}}: \{0,1,2,3\} \times \mathbb{R}^{60} \rightarrow \mathbb{R}^{59\cdot 2}:$$

$$\mathcal{N}_{oldsymbol{
ho}}\left(egin{bmatrix} z_t \ \mathbf{k}_t \end{bmatrix}
ight) = egin{bmatrix} a_t^1 \ \ldots \ a_t^{59} \ \lambda_t^1 \ \ldots \ \lambda_t^{59} \end{bmatrix}$$

such that

$$\mathbf{G}\left(egin{bmatrix} z_t \ \mathbf{k}_t \end{bmatrix}, \mathcal{N}_{oldsymbol{
ho}}\left(egin{bmatrix} z_t \ \mathbf{k}_t \end{bmatrix}
ight)
ight)pprox \mathbf{0}$$

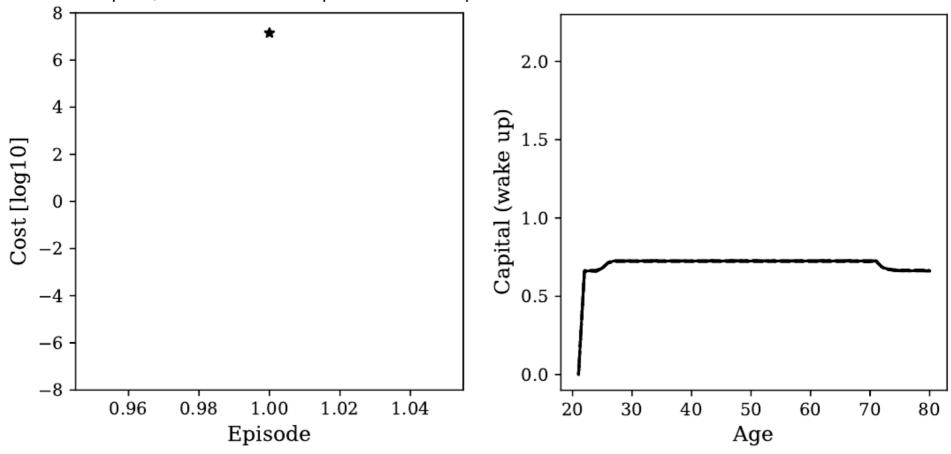

$$\hat{\mathbf{x}}_{+} = \begin{bmatrix} z_{+} \\ 0 \\ \hat{a}^{[1:N-1]}(\mathbf{x}) \end{bmatrix}$$

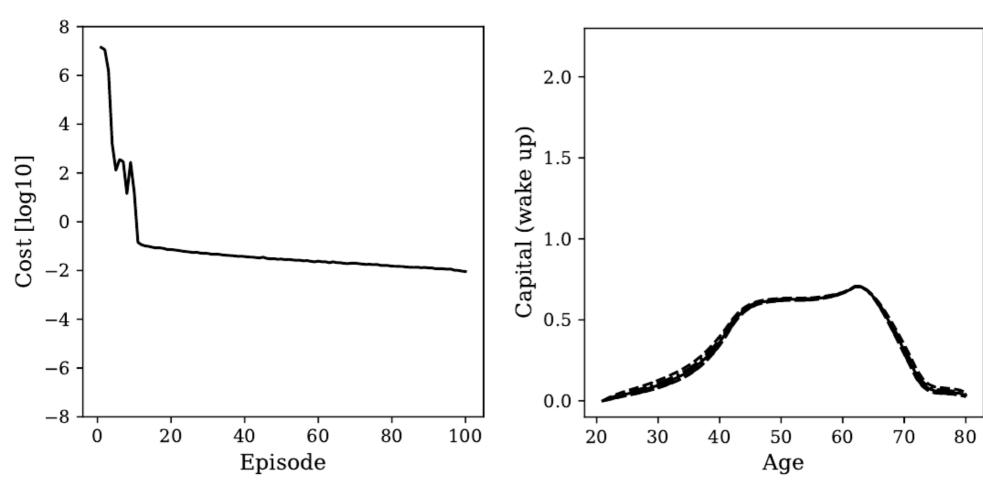

Def.: **Episode**: the set of T simulated periods.

**Epoch**: when the whole dataset is passed through the algorithm.

Per epoch, the neural network parameters are updated T/m times.

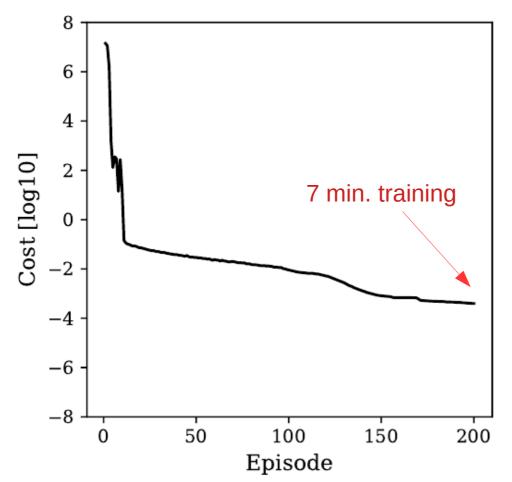

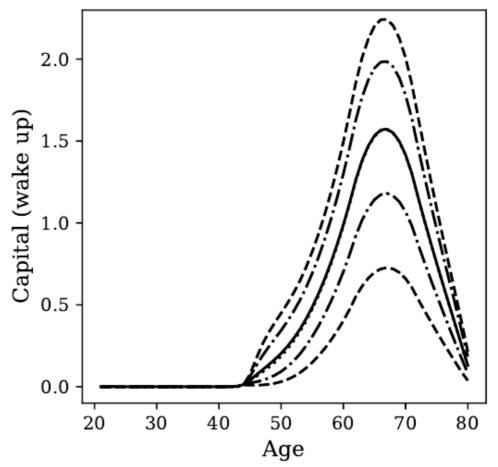

Typical runtime: 2.1 [sec/Episode]

Learning rate: 10<sup>-5</sup> Batch size: 1,000; 10,000 periods/Episode

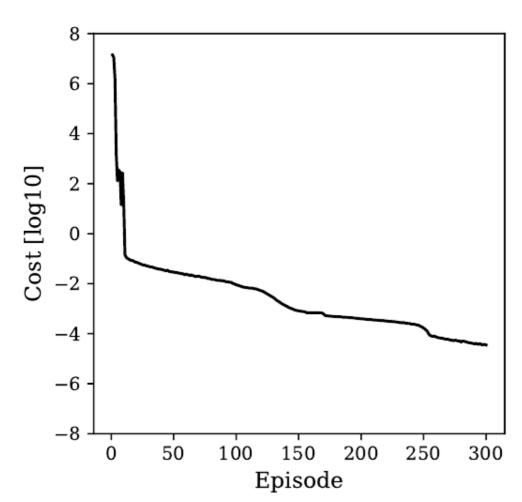

Solid line: **mean** over 10,000 simulated periods
Dash-dotted lines show the **10th and 90th percentile**Dashed lines show the **0.1th and 99.9th percentile**.

Typical runtime: 2.1 [sec/Episode]

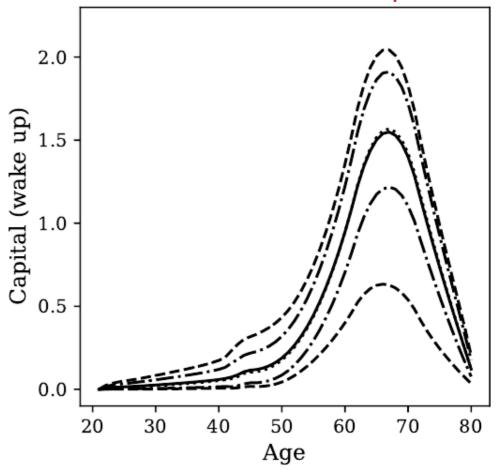

Learning rate: 10<sup>-5</sup>

shock  $1:\delta=0.5,\xi=0.85, \text{ shock } 2:\delta=0.5,\xi=1.15, \text{ shock } 3:\delta=0.9,\xi=0.85 \text{ shock } 4:\delta=0.9,\xi=1.15$ 

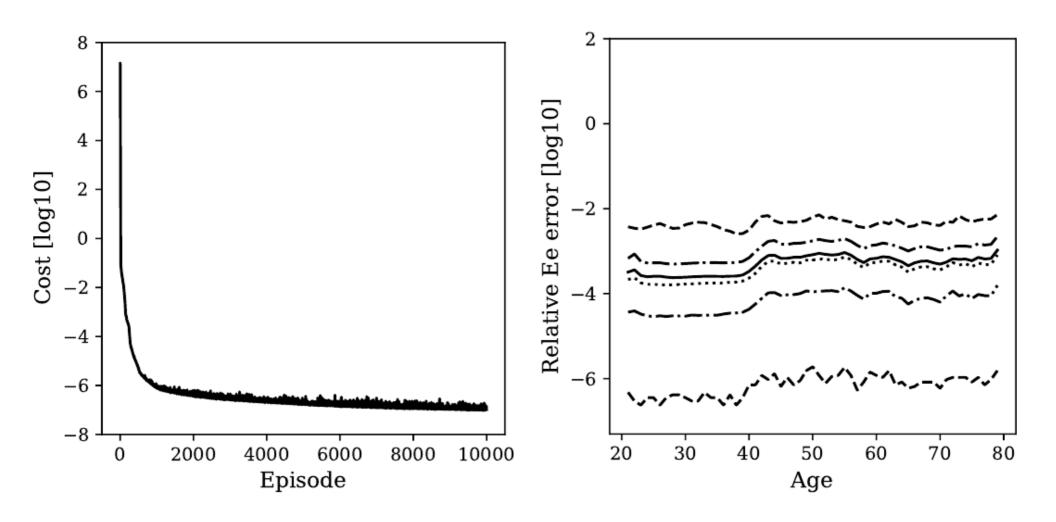

shock  $1:\delta=0.5,\xi=0.85, \text{ shock } 2:\delta=0.5,\xi=1.15, \text{ shock } 3:\delta=0.9,\xi=0.85 \text{ shock } 4:\delta=0.9,\xi=1.15$ 

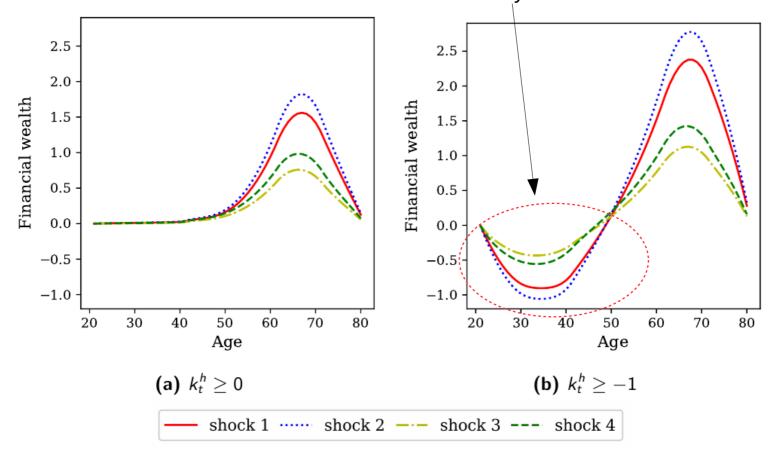

#### Loosening the borrowing constraint

**Financial wealth** = value of the capital saved in the last period after returns realized.

Young agents take up debt, pay back later as their labour endowment increases in their later years.

shock  $1: \delta = 0.5, \xi = 0.85$ , shock  $2: \delta = 0.5, \xi = 1.15$ , shock  $3: \delta = 0.9, \xi = 0.85$  shock  $4: \delta = 0.9, \xi = 1.15$ 

#### **Summary**

- Deep learning based, **grid-free**, **global solution method** to compute approximate recursive equilibria for discrete-time dynamic stochastic economic models with very high-dimensional state spaces.
- Key innovation: use the implied error in the optimality conditions as loss function → training data can be generated at virtually zero cost.
- comprehensive, scalable and flexible method to address rich models.
